

COVID-19 Major Variants¹ (in the U.S.)

	Original strain (or Wild-type)	Delta	Omicron (BA.1) and BA.2	BA2.12 (Variant of Omicron)	BA.4 and BA.5 (Variants of Omicron)
U.S. timeline	- March 2020 to June 2021 - Estimated 540,000 deaths	- June to December 2021 - Estimated 274,000 deaths	- December 2021 to May 2022 - Estimated 118,000 deaths	April/May 2022 to June 2022	July 2022 to present
What are typical signs of illness? (Note: some folks with COVID do not have these signs of illness)	- Cough - Fever - Shortness of breath - Loss of taste or smell - Pneumonia (infection in the lungs) - Others could occur	More common: - Cough - Sore throat - Runny nose Less common but still can occur: - Fever - Shortness of breath - Pneumonia - Loss of taste or smell - Stomach problems, diarrhea			More common: - Sore throat - Runny nose - Fever - Headache - Stomach problems, diarrhea Less common but still can occur: - Cough - Shortness of breath - Pneumonia - Loss of taste or smell
Incubation Period ²	Around 5 days	Around 4 days	2-4 days	To be determined	To be determined
Number of people 1 person can infect?3	Around 3	6-7	7-14	To be determined	To be determined
How severe is it?		More severe than the original strain	At least as severe as the original strain, though less severe than Delta.	Possibly more severe than <u>original strain</u>	In studies done on animals, BA.4 and BA.5 may cause more severe disease
How do <u>vaccines</u> <u>work</u> ? ⁴	Strong prevention of infection and severe disease	- Moderate prevention of infection- Strong prevention of severe disease	- Limited prevention of infection - <u>Moderate to strong prevention</u> of <u>severe disease</u>		- To be determined - <u>Lab data suggest limited</u> prevention of infection
Does treatment⁵ work?	All treatments (Remdesivir, monoclonal antibodies, Paxlovid, etc) work.		Resistant to some monoclonal antibodies		Resistant to additional monoclonal antibodies
Am I protected if I already had COVID?			Evades immunity built from other strains (more easily infects vaccinated people or those who have had COVID)	Evades immunity built from earlier forms of Omicron (BA.1 and BA.2)	- May have some power to evade immunity built from Omicron (BA.1 and BA.2) - May have more power to evade immunity built from other variants
Public health impact	The original virus that started the pandemic	Much <u>more</u> <u>transmissible</u> than original strain	Causes high rates of hospitalization and death among among children and the elderly because it spreads and reinfects easily	When BA.2.12.1 was dominant, U.S. confirmed over 100,000 cases daily, on average, for first time since February 2022	- U.S. continues to confirm over 100,000 COVID cases daily, on average - Doubled hospitalizations since May 2022
1 Alpha, which caused an <u>estimated 40,000 deaths</u> in the United States from March-June 2021, is not included. 2 Time from exposure to testing positive; this helps you know when to test after an exposure.			3 How many people each infected person will spread the virus to, on average, in a group with no immunity. The higher the number, the more infectious. Real-world numbers may be lower. 4 Vaccine effectiveness also depends on boosters, time since vaccination, age, and immuno-status. 5 Treatments include Remdesivir, Paxlovid, and monoclonal antibodies.
